

Sparse PCA with Multiple Components

Ryan Cory-Wright, Jean Pauphilet

Website: jeanpauphilet.github.io

Principal Component Analysis (PCA)

Idea

For a high-dimensional dataset X, find a few orthogonal directions (r) that explain most of the variance

Algorithm

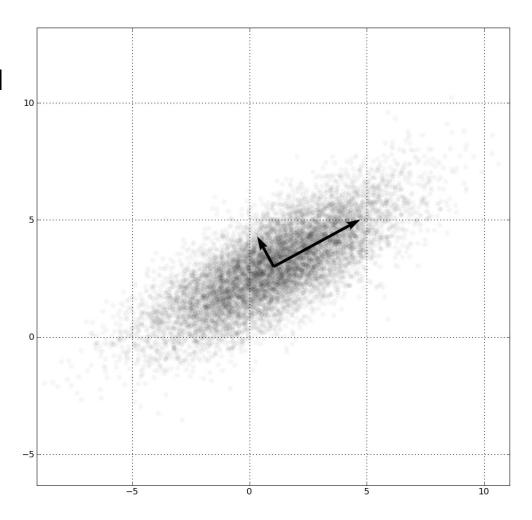

Dataset $X \in \mathbb{R}^{n \times p}$

Compute its covariance/correlation matrix $m{\mathcal{Z}}$ Solve

$$\max_{\boldsymbol{U} \in \mathbb{R}^{p \times r}} \ \langle \boldsymbol{U} \boldsymbol{U}^{\top}, \boldsymbol{\Sigma} \rangle \text{ s.t. } \boldsymbol{U}^{\top} \boldsymbol{U} = \mathbb{I}$$

Compress dataset into smaller one

$$X_{\text{comp}} \coloneqq U_{[1:r]} X \in \mathbb{R}^{n \times r}$$

Optimization for PCA

$$\max_{oldsymbol{U} \in \mathbb{R}^{p imes r}} \ \langle oldsymbol{U} oldsymbol{U}^ op, oldsymbol{\Sigma}
angle \ ext{s.t.} \ oldsymbol{U}^ op oldsymbol{U} = \mathbb{I}$$

It looks hard...

- Maximizing a convex function
- Non-convex quadratic constraints (orthogonality)

... can be solved very efficiently

- Solution obtained via truncated SVD
- For r=1, orthogonality constraint is trivial to satisfy (scaling)
- For r > 1, greedy is optimal
 i.e., solve for r=1, deflate the covariance matrix, repeat
 Deflation naturally takes care of orthogonality!

Why sparsity in PCA?

- Interpretability
 New coordinates (PCs) can be dense combination of all features
- Consistency in high-dimensional settings When $p/n \to \alpha$, PCA can be inconsistent

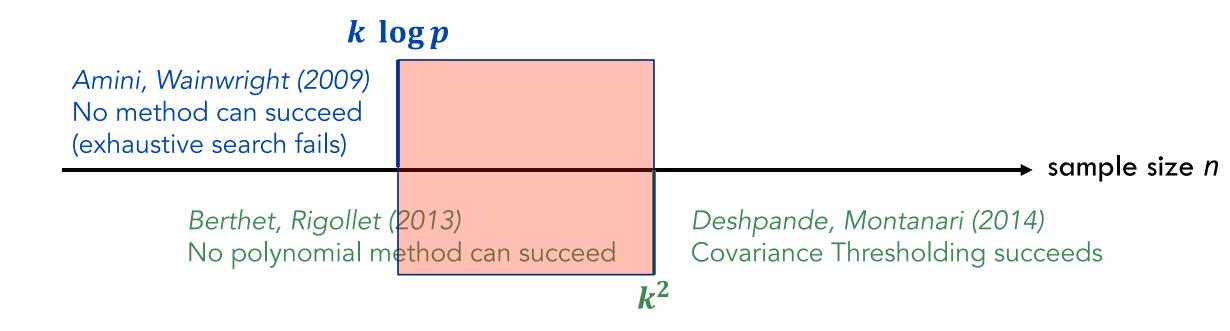

Solution Sparsity

$$\max_{\boldsymbol{u} \in \mathbb{R}^p} \quad \langle \boldsymbol{\Sigma}, \boldsymbol{u} \boldsymbol{u}^\top \rangle \text{ s.t. } \|\boldsymbol{u}\|_2^2 = 1, \|\boldsymbol{u}\|_0 \leq k$$

PCA requires in the order of $n \gtrsim p$ samples

sparse PCA requires $n \gtrsim k \log p$

Why "provably optimal" algorithms can help?

Opportunity for optimization!

From r=1 to r>1

Jungle of algorithms for sparse PCA with r=1 PC

However, for r > 1, ...

- Deflation approach is no longer optimal
- Deflation no longer guarantees orthogonality (feasibility)
- Assuming perfect support detection, estimation is no longer trivial

Sparse PCA With Multiple Components

Overall problem Explain dataset using sparse and mutually orthogonal components

$$\max_{m{U} \in \mathbb{R}^{p imes r}} \ raket{m{U}m{U}^ op, m{\Sigma}} \ ext{s.t.} \ m{U}^ op m{U} = \mathbb{I}, \ \|m{U}\|_0 \leq k.$$

Our Contributions

- 1. Reformulation as as rank and sparsity constrained problem
- 2. Tight and scalable semidefinite relaxation w. strong valid inequalities
- 3. Coupled w. good heuristics, provably near-optimal solutions for $p \approx 100$

Reformulation

$$\max_{\boldsymbol{U} \in \mathbb{R}^{p \times r}} \langle \boldsymbol{U} \boldsymbol{U}^{\top}, \boldsymbol{\Sigma} \rangle \quad \text{s.t.} \quad \boldsymbol{U}^{\top} \boldsymbol{U} = \mathbb{I}, \ \|\boldsymbol{U}\|_{0} \leq k.$$

$$\max_{\substack{\mathbf{Z} \in \{0,1\}^{p \times r} \\ \langle \mathbf{E}, \mathbf{Z} \rangle < k}} \max_{\mathbf{U} \in \mathbb{R}^{p \times r}} \left[\langle \mathbf{U} \mathbf{U}^{\top}, \mathbf{\Sigma} \rangle \right] \text{ s.t. } \mathbf{U}^{\top} \mathbf{U} = \mathbb{I}, \mathbf{U}_{i,t} = 0 \text{ if } Z_{i,t} = 0, \forall i \in [p], \forall t \in [r],$$

Introduce

 $\langle \boldsymbol{E}, \boldsymbol{Z} \rangle \leq k$

$$oldsymbol{Y}^t := oldsymbol{U}_t oldsymbol{U}_t^ op, \quad oldsymbol{Y} := \sum_{t \in [r]} oldsymbol{Y}^t = oldsymbol{U} oldsymbol{U}^ op$$

$$\langle oldsymbol{U}oldsymbol{U}^ op, oldsymbol{\Sigma}
angle
ightarrow \langle oldsymbol{Y}, oldsymbol{\Sigma}
angle$$

$$\boldsymbol{U}^{\top}\boldsymbol{U} = \mathbb{I} \to \operatorname{tr}(\boldsymbol{Y}^t) = 1, \ \langle \boldsymbol{Y}^t, \boldsymbol{Y}^{t'} \rangle = 0 \ (t \neq t')$$

$$U_{i,t} = 0 \text{ if } Z_{i,t} = 0 \to Y_{i,j}^t = 0 \text{ if } Z_{i,t} = 0$$

$$\max_{\boldsymbol{Z} \in \{0,1\}^{p \times r}: \; \boldsymbol{Y} \in \mathcal{S}^p, \boldsymbol{Y}^t \in \mathcal{S}^p_+} \max_{\boldsymbol{Y} \in \mathcal{S}^p, \boldsymbol{Y}^t \in \mathcal{S}^p_+} \left[\langle \boldsymbol{Y}, \boldsymbol{\Sigma} \rangle \right] \text{ s.t. } \left[\operatorname{tr}(\boldsymbol{Y}^t) = 1, \; \forall t \in [r], \; \langle \boldsymbol{Y}^t, \boldsymbol{Y}^{t'} \rangle = 0, \forall t, t' \in [r], t \neq t', \right]$$

$$Y_{i,j}^t = 0 \text{ if } Z_{i,t} = 0, \ \forall t \in [r], i, j \in [p]$$

$$Y = \sum_{t=1}^{r} Y^{t}$$
, Rank $(Y^{t}) = 1$, $\forall t \in [r]$.

Reformulation

$$\max_{\substack{\mathbf{Z} \in \{0,1\}^{p \times r}: \ \mathbf{Y} \in \mathcal{S}^{p}, \mathbf{Y}^{t} \in \mathcal{S}_{+}^{p} }} \langle \mathbf{Y}, \mathbf{\Sigma} \rangle \text{ s.t. } \operatorname{tr}(\mathbf{Y}^{t}) = 1, \ \forall t \in [r], \qquad \mathbf{Y} = \sum_{t \in [r]} \mathbf{Y}^{t} \preceq \mathbb{I}$$

$$Y_{i,j}^{t} = 0 \text{ if } Z_{i,t} = 0, \ \forall t \in [r], i, j \in [p],$$

$$\mathbf{Y} = \sum_{t=1}^{r} \mathbf{Y}^{t}, \ \operatorname{Rank}(\mathbf{Y}^{t}) = 1, \ \forall t \in [r].$$

PROPOSITION 1. Consider r matrices, $\mathbf{Y}^t \in \mathcal{S}^p_+$, such that $\operatorname{tr}(\mathbf{Y}^t) = 1$ and $\operatorname{Rank}(\mathbf{Y}^t) = 1$. Then, $\sum_{t \in [r]} \mathbf{Y}^t \preceq \mathbb{I}$ if and only if $\langle \mathbf{Y}^t, \mathbf{Y}^{t'} \rangle = 0 \ \forall t, t' \in [r] : t \neq t'$.

Sparse and low-rank reformulation

$$\max_{\substack{\mathbf{Z} \in \{0,1\}^{p \times r}: \mathbf{Y} \in \mathcal{S}^{p}, \mathbf{Y}^{t} \in \mathcal{S}_{+}^{p} \\ \langle \mathbf{E}, \mathbf{Z} \rangle \leq k}} \max_{\substack{\mathbf{Y} \subseteq \{0,1\}^{p \times r}: \mathbf{Y} \in \mathcal{S}_{+}^{p} \\ \langle \mathbf{E}, \mathbf{Z} \rangle \leq k}} \langle \mathbf{Y}, \mathbf{\Sigma} \rangle \text{ s.t. } \mathbf{Y} \preceq \operatorname{Diag}\left(\min\left(\mathbf{e}, \sum_{t} \mathbf{Z}_{t}\right)\right), \mathbf{Y} = \sum_{t=1}^{r} \mathbf{Y}^{t},$$

$$\operatorname{tr}(\mathbf{Y}^{t}) = 1, \ \forall t \in [r], \ Y_{i,j}^{t} = 0 \ \text{if } Z_{i,t} = 0 \ \forall t \in [r], i, j \in [p],$$

$$\operatorname{Rank}(\mathbf{Y}^{t}) = 1, \ \forall t \in [r].$$

Next steps (in the paper)

- Relaxation: SDP/SOC for rank, big-M for logical constraints
- Strengthened formulation via symmetry-breaking inequalities
- Strengthened formulation via valid inequalities linking \mathbf{Y}^t and \mathbf{Z}_t
- Relax-round-then-estimate heuristics

Valid Inequalities via Individual Sparsity Budgets

Suppose t^{th} component k_t sparse with $\sum_t k_t =: k$. Impose

$$\left(\sum_{j=1}^{p} |Y_{i,j}^{t}|\right)^{2} \le k_{t} Y_{i,i}^{t} Z_{i,t} \quad \forall i \in [p], \forall t \in [r]$$

$$\sum_{i \in [p]: i \ne j} {Y_{i,j}^{t}}^{2} \le (k_{t} - 1) Z_{j,t} (Z_{j,t} - Y_{j,j}^{t}) \quad \forall j \in [p].$$

 \rightarrow Tightens relaxation substantially but requires knowledge of k_t 's

Feasible Solutions via Alternating Minimization

A Lagrangean Relaxation of Sparse PCA

$$\max_{\substack{\mathbf{Z} \in \{0,1\}^{p \times r}: \ \mathbf{Y} \in \mathcal{S}_{+}^{p}, \mathbf{Y}^{t} \in \mathcal{S}_{+}^{p} \\ \langle \mathbf{e}, \mathbf{Z}_{t} \rangle \leq k_{t}}} \sum_{\substack{\mathbf{Y} \in \mathcal{S}_{+}^{p}, \mathbf{Y}^{t} \in \mathcal{S}_{+}^{p} \\ \langle \mathbf{e}, \mathbf{Z}_{t} \rangle \leq k_{t}}}} \sum_{\substack{t \in [r]}} \langle \mathbf{Y}^{t}, \mathbf{\Sigma} \rangle - \lambda \sum_{\substack{t, t' \in [r]: t \neq t'}} \langle \mathbf{Y}^{t}, \mathbf{Y}^{t'} \rangle \text{ s.t. } \operatorname{tr}(\mathbf{Y}^{t}) = 1, \ \forall t \in [r], \\ Y_{i,j}^{t} = 0 \text{ if } Z_{i,t} = 0, \ \forall t \in [r], i, j \in [p], \\ \operatorname{Rank}(\mathbf{Y}^{t}) = 1, \ \forall t \in [r].$$

 $\lambda > 0$ a penalty parameter

Fix all but one PC ——— Single component sparse PCA

Alternating minimization High-quality solutions

Code available on GitHub: Tyancorywright/MultipleComponentsSoftware

Application I: pitprops dataset (p=13), r=6 PCs

Lu and Zhang, MP (2011)

"we deduce that for the Pitprops data, it seems not possible to extract six highly sparse (e.g., around 60 zero loadings), nearly orthogonal and uncorrelated PCs while explaining most of variance as they may not exist."

\overline{r}	k_t		Alg. 1		Alg. 2			Branch-and-Bound

Pitprops data

Application II: Performance on UCI Datasets

- Fix k=15,30, r=3
- Compute worst bound, best AM solution over rank-3 allocations of sparsity budget

Dataset	p	r	k	Enumerated					
			k	k_t	Obj.	Rel. ga	ap (%)	Viol.	
Pitprops	13	3	15	(7, 6, 2)	0.595		3.67%	0.002	
			30	(10, 10, 10)	0.650		0.28%	0.005	
Ionosphere	34	3	15	(7, 6, 2)	0.299		0%	0	
			30	(11, 10, 9)	0.402		2.35%	0	
Geographical	68	3	15	(6, 5, 4)	0.221		0%	0	
			30	(12, 12, 6)	0.420		0%	0	
Communities	101	3	15	(6, 5, 4)	0.142		0.01%	0	
			30	(11, 11, 8)	0.247		0.17%	0	

The average semidefinite relaxation gap is less than 1%!

Application III: US Senate Voting Patterns 2021-2022

Problem setting

Explain voting patterns in 117th senate

- n=100 data points (senators)
- p=839 features (bills/amendments/noms...)
 - Screened out p=17 unanimous votes
- Compute two 5-sparse PCs via SOC relax+greedy rounding, score senators

Results First PC Second PC Initial vote on Inflation Revenues from leasing Reduction Act (IRA) oil/gas on federal land Another vote on IRA Extend Trump tax cuts Lower cost of Insulin Deficit neutral fund for Another vote on IRA catch-and-release Amendment to IRA Update text of 2021-22 budget Pass 2021-22 budget

All five votes on same day!

All five votes on same day!

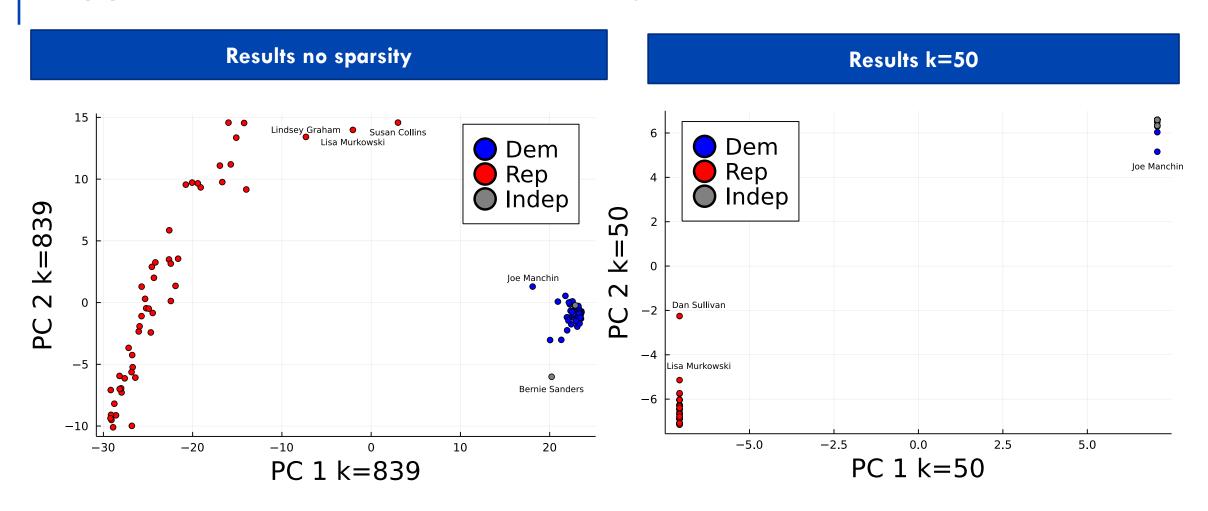

All five votes on same day!

The July 2022 "Inflation Reduction Act"

The Feb 2021 "American Rescue Plan" and 3 proposed amendments All five votes on same day!

Both PCs perfect classifiers by party!
Plots not vey interesting, so increase k

Application III: US Senate Voting Patterns 2021-2022

Conclusion

Sparse PCA with r>1 PCs remains a largely open problem

Sparse PCA with r>1 PCs is significantly more challenging than the r=1 case

Orthogonality → rank constraints

Semidefinite Relaxation + Alternating Minimization Solves Sparse PCA to (Near) Optimality

- Bound gaps of 1%-5% in practice, depending on application
- Key is to use good valid inequalities to tighten formulations

Thank you!
